Quiz, 10 questions

 $a^{[2](12)}$ denotes the activation vector of the 2^{nd} layer for the 12^{th} training example.

Correct

1/1 points

2.

The tanh activation usually works better than sigmoid activation function for hidden units because the mean of its output is closer to zero, and so it centers the data better for the next layer. True/False?

True

Correct

Yes. As seen in lecture the output of the tanh is between -1 and 1, it thus centers the data which makes the learning simpler for the next layer.

False

1/1 points

3.

Which of these is a correct vectorized implementation of forward propagation for layer l, where $1 \leq l \leq L$?

$$ullet \ A^{[l]} = g^{[l]}(Z^{[l]})$$

$$igcup Z^{[l]} = W^{[l]} A^{[l]} + b^{[l]}$$

$$ullet \ A^{[l+1]} = g^{[l+1]}(Z^{[l]})$$

Shallow Neural Networks $g^{[l]}(Z^{[l]})$

4.

You are building a binary classifier for recognizing cucumbers (y=1) vs. watermelons (y=0). Which one of these activation functions would you recommend using for the output layer?

ReLU

Leaky ReLU

sigmoid

Correct

Yes. Sigmoid outputs a value between 0 and 1 which makes it a very good choice for binary classification. You can classify as 0 if the output is less than 0.5 and classify as 1 if the output is more than 0.5. It can be done with tanh as well but it is less convenient as the output is between -1 and 1.

tanh

5.

Consider the following code:

Shallow Neural Networks.randn(4,3)

10/10 points (100.00%)

Quiz, 10 questions

B = np.sum(A, axis = 1, keepdims = True)

What will be B.shape? (If you're not sure, feel free to run this in python to find out).

(4, 1)

Correct

Yes, we use (keepdims = True) to make sure that A.shape is (4,1) and not (4,). It makes our code more rigorous.

- (, 3)
- (1, 3)
- (4,)

6.

Suppose you have built a neural network. You decide to initialize the weights and biases to be zero. Which of the following statements is true?

Each neuron in the first hidden layer will perform the same computation. So even after multiple iterations of gradient descent each neuron in the layer will be computing the same thing as other neurons.

Correct

Each neuron in the first hidden layer will perform the same computation in the first iteration. But after one iteration of gradient descent they will learn to compute different things because we have "broken symmetry".

1/9/2018	Neural Networks and Deep Learning - Home Coursera	
	Each neuron in the first hidden layer will compute the same thing,	
	but neurons in different layers will compute different things, thus	
Shallow Ne	eural Natworksomplished "symmetry breaking" as described in 10/10 points (100,	.00%)

	7.	
	Logistic regression's weights w should be initialized randomly rather than to	
	all zeros, because if you initialize to all zeros, then logistic regression will fail	
	to learn a useful decision boundary because it will fail to "break symmetry",	
	True/False?	
	True	
	False	
	Correct	
	Yes, Logistic Regression doesn't have a hidden layer. If you initialize	
	the weights to zeros, the first example x fed in the logistic regression	
	will output zero but the derivatives of the Logistic Regression depend	
	on the input x (because there's no hidden layer) which is not zero. So	
	at the second iteration, the weights values follow x's distribution and	
	are different from each other if x is not a constant vector.	
	are different from each other if x is not a constant vector.

	8.	
	You have built a network using the tanh activation for all the hidden units.	
	You initialize the weights to relative large values, using	
	np.random.randn(,)*1000. What will happen?	
	This will cause the inputs of the tanh to also be very large, thus	
	causing gradients to also become large. You therefore have to set $lpha$	
	to be very small to prevent divergence; this will slow down	
	to be very small to prevent divergence, this will slow down	

learning.

It doesn't matter. So long as you initialize the weights randomly gradient descent is not affected by whether the weights are large Shallow Neural Netswarks

10/10 points (100.00%)

Quiz, 10 questions

This will cause the inputs of the tanh to also be very large, thus causing gradients to be close to zero. The optimization algorithm will thus become slow.

Correct

Yes. tanh becomes flat for large values, this leads its gradient to be close to zero. This slows down the optimization algorithm.

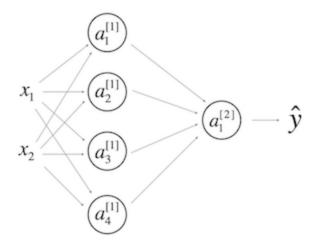

This will cause the inputs of the tanh to also be very large, causing the units to be "highly activated" and thus speed up learning compared to if the weights had to start from small values.
